

EXP 3:

Class Diagram

Aim:

To model the static structure of a software system by identifying its classes, their attributes, operations, and the relationships among objects, thereby establishing a blueprint for system design and implementation.

Procedure:

1. Identify the core classes (entities/objects) of the system along with their attributes (data fields with types) and operations (methods).
2. Define relationships between classes: associations (with multiplicity constraints such as 1:1, 1:N, 0..*), dependencies, aggregations, and compositions.
3. Incorporate enumeration classes to represent fixed sets of values (e.g., ActivityType, Priority, Stage) used across the system.
4. Render the class diagram using UML notation; validate class attributes, relationship cardinalities, and navigability against system requirements, then capture a snapshot.

Output:

Result:

A fully annotated UML class diagram depicting class schemas with typed attributes, enumeration definitions, multiplicity-constrained associations, and navigability annotations for the target CRM system domain.
